DESCRIPTION

CALCIUM RECEPTOR MODULATING COMPOUND AND USE THEREOF

5 BACKGROUND OF THE INVENTION

Field of the Invention

The present invention relates to heterocyclic compounds having calcium-sensing receptor (CaSR, hereinafter simply referred to as Ca receptor) modulating (agonistic or antagonistic) activity, pharmaceutical compositions containing them and intermediate compounds useful for synthesizing them.

Background Art

15 Calcium ion (hereinafter simply referred to as Ca) plays an essential role to maintain and modulate functions of various cells such as endocrine and exocrine cells, etc., in addition to nerve and muscle. For this reason, the blood Ca level is strictly maintained in a narrow range.

20 Parathyroid hormone (PTH) plays a central role in maintaining this blood Ca level. Therefore, secretion of PTH from parathyroid gland responds sharply to change in the blood Ca level and is must be modulated according to this. In fact, when the blood Ca level is changed, the

25 blood PTH level is rapidly changed in response to this.

The possibility of a mechanism by which the extracellular Ca concentration is sensed by parathyroid gland cells and the information transmitted into cells has been pointed out early by Brown et al. In 1993, they succeeded in the cloning and characterization of a Ca-sensing receptor (CaSR; hereinafter, simply referred to as Ca receptor) from bovine parathyroid (Nature, 366, 575-580(1993)).

The Ca receptor is composed of a large terminal extracellular region spanning 600 amino acids at the N-terminal, having seven transmembrane spanning domains like other G protein coupled receptors, and an intracellular region consisting of 200 or less amino acids at the caboxyl C-terminal.

It is considered that, when the extracellular Ca concentration is increased, phospholipase (PL)-C is activated, leading to increase in the intracellular Ca concentration and inhibition of PTH secretion due to increase in inositol triphosphate (IP₃). Since when a high value of the extracellular Ca concentration is maintained, the intracellular Ca concentration is thereafter increased continuously, it is considered that influx of Ca from the outside of a cell is also promoted. PL-A₂ and D are activated due to increase in extracellular Ca, but there is a possibility that these are via protein kinase (PK)-C and the like which are activated at the same time via Ca

receptor. The Ca receptor also inhibits adenylyl cyclase via Gi protein or via arachidonic acid production due to activation of PL-A₂ and decreases intracellular cyclic AMP (Bone, 20, 303-309 (1997)).

5 Ca receptor mRNA is expressed in many tissues, and the expression amount is high, in parathyroid gland, thyroid gland C cell, medulla and cortex thick ascending limb (MTAL and CTAL) of kidney uriniferous tubule, intramedullary collecting tubule (IMCD) and encephalic subfornical organ
10 (SFO) and hippocampus (Bone, 20, 303-309 (1997)). In addition, expression is recognized in many tissues such as encephalic hypothalamus, cerebellum and olfactory nucleus, regions other than TAL of renal uriniferous tubule, lung, stomach, pancreas, intestine and skin. Since the Ca
15 receptor is present in various tissues, its physiological function has yet to be fully understood. However, it is expected that the Ca receptor modulating (agonistic or antagonistic) drug would provide for a novel treatment of various disease states which include the following:

20 1. Drugs for Treating Bone Diseases

Since the anabolic activity is manifested by intermittent administration of PTH, Ca receptor modulating drugs which are considered to be able to regulate secretion of PTH are promising as a drug for treating osteoporosis.

25 In addition, Ca receptor modulating drugs which are

selectable for thyroid gland C cell may be also effective for treating osteoporosis by stimulation of calcitonin secretion. Whether the same Ca receptor as that of parathyroid gland is present in osteoblast, osteoclast and bone cell or not is disputable. However, some Ca-sensing mechanism is assuredly present therein and, therefore, drugs which directly act on them can be expected as a drug for treating bone diseases.

2. Kidney-Acting Drugs

Handling of water and mineral in kidney is not only based on the results of function as a target organ for hormones, such as PTH, vitamin D etc., but also the Ca receptor in kidney is presumed to function in a response to the Ca concentration and the magnesium ion concentration in the extracellular fluid (Kidney Int, 50, 2129-2139 (1996)). Further, it is also considered that Ca receptor modulating drugs may modulate the blood amount in kidney, the amount of glomerulus filtration, renin secretion and activation of vitamin D in addition to control of influx and efflux of water and mineral.

3. Central Nervous System and Endocrine-Acting Drugs

Ca receptor is present in almost all areas in the central nervous system, and is remarkably expressed, in particular, in the hippocampus, cerebellum and subfornical organ (Brain Res, 744. 47-56 (1997)). Although the details

of the function are still unclear, the term of Ca receptor expression after birth in the hippocampus is consistent with the term of acquisition of LTP (Long Tightening Phenomenon) (Develop Brain Res, 100, 13-21 (1997)) and, therefore, the relationship with memory and learning can be presumed. Therefore, Ca receptor modulating drugs which are high in brain-blood barrier permeability and selective for the central nerve system may be utilized for treating Alzheimer's disease. In addition, since dry mouth occurs in hypercalcemic patient, Ca receptor modulating drugs may control them. The presence of Ca receptor in mouse pituitary gland cells which secrete ACTH has been reported (Mol Endocrinol, 10, 555-565 (1996)). It is also considered that Ca receptor modulating drugs can be applied to Sheehann's syndrome and hypopituitarism or hyperpituitarism.

4. Digestive System-Acting Drugs

It is considered that a Ca receptor is present in the Auerbach nerve plexus of the digestive tract and controls intestinal tract motion. Constipation is known in hypercalcemic patients and stimulation of digestive tract motion is known in hypocalcemic patients in clinical tests. The existence of a Ca receptor in the gastrin secreting cell (G cell) of the stomach has been reported (J. Clin Invest, 99, 2328-2333 (1997)), and intestinal tract

absorption, constipation, diarrhea, defecation and secretion of acid in the stomach may be controlled by drugs which act on a Ca receptor in the digestive tract. Further, it has been found that a Ca receptor is present in human colon cancer cell strains and it controls c-myc expression and proliferation (Biochem Biophys Res Commun, 232, 80-83 (1997)), this is better consistent with the fact that the Ca uptake and sideration of colon and rectum cancers exhibit the negative correlation and, therefore, Ca receptor regulating drugs can be expected also as a drug for preventing and treating such cancers.

wherein A-4 denote the same meaning as that of A, R^{16} denotes an optionally substituted carbon atom, and the other symbols are as defined above.

In step L, Compound (II-10) is prepared by a reaction for leaving a carboxyl-protecting group.

All conventional methods used in a reaction for leaving a carboxyl-protecting group, for example, hydrolysis, reduction and elimination using a Lewis acid can be applied to the present reaction. It is preferable that hydrolysis is carried out in the presence of a base or an acid. Examples of the suitable base include inorganic bases such as alkali metal hydroxide (e.g. sodium hydroxide and potassium hydroxide), alkaline earth metal hydroxide (e.g. magnesium hydroxide and potassium hydroxide), alkali

metal carbonate (e.g. sodium carbonate and potassium carbonate), alkaline earth metal carbonate (e.g. magnesium carbonate and calcium carbonate), alkali metal bicarbonate (e.g. sodium bicarbonate and potassium bicarbonate), alkali metal acetate (e.g. sodium acetate and potassium acetate), alkaline earth metal phosphate (e.g. magnesium phosphate and calcium phosphate) and alkali metal hydrogen phosphate (e.g. disodium hydrogen phosphate and dipotassium hydrogen phosphate), and organic bases such as trialkylamine (e.g. trimethylamine and triethylamine), picoline, N-methylpyrrolidine, N-methylmorpholine, 1,5-diazabicyclo[4.3.2]non-5-ene, 1,4-diazabicyclo[2.2.2]non-5-ene and 1,8-diazabicyclo[4.3.0]-7-undecene. Hydrolysis using a base is carried out in water or a hydrophilic organic solvent or a mixed solvent in many cases. Examples of the suitable acid include formic acid, hydrobromic acid and sulfuric acid.

The present hydrolysis reaction is usually carried out in an organic solvent, water or a mixed solvent thereof. A reaction temperature is not particularly limited, but is appropriately selected depending on a kind of a carboxyl-protecting group and an elimination method. Elimination using a Lewis acid is carried out by reacting Compound (II-9) or a salt thereof with a Lewis acid, for example, trihalogenated boron (e.g. boron trichloride and boron

trifluoride), tetrahalogenated titanium (e.g. titanium tetrachloride and titanium tetrabromide), and halogenated aluminium (e.g. aluminium chloride and aluminium bromide), or an organic acid (e.g. trichloroacetic acid and trifluoroacetic acid). This elimination reaction is preferably carried out in the presence of a cation scavenger (e.g. anisole and phenol) and is usually carried out in a solvent such as nitroalkane (e.g. nitromethane and nitroethane), alkylene halide (e.g., methylene chloride and ethylene chloride), diethyl ether, carbon disulfide, and a solvent having no adverse effect on the reaction. These solvents may be used as a mixture thereof.

It is preferable that elimination by reduction is applied to elimination of a protecting group such as halogenated alkyl (e.g. 2-iodoethyl and 2,2,2-trichloroethyl) ester, and aralkyl (e.g. benzyl) ester. Examples of a reduction method using in the present elimination reaction include the conventional catalytic reduction in the presence of a combination of a metal (e.g. zinc and zinc amalgam) or a salt of a chromium compound (e.g. chromate chloride and chromate acetate) and an organic or inorganic acid (e.g. acetic acid, propionic acid and hydrochloric acid); or the conventional metal catalyst (e.g. palladium carbon and Raney nickel). A reaction temperature is not particularly limited, but a reaction is

carried out under cooling, at room temperature or under warming.

The thus obtained Compound (II-10) can be isolated and purified by the known isolating and purifying methods, for example, concentration, concentration under the reduced pressure, extraction with solvent, crystallization, recrystallization, transfer dissolution and chromatography.

Although the reaction is usually carried out in the conventional solvent such as water, alcohols such as methanol, ethanol and the like, acetone, dioxane, acetonitrile, chloroform, methylene chloride, ethylene chloride, tetrahydrofuran, ethyl acetate, N,N-dimethylformamide and pyridine, the reaction may be carried out in any other organic solvents as long as they have no

adverse effect on the reaction. These conventional solvents may be used as a mixture with water.

Example 15

Ethyl 7,7-dimethyl-5-(2-pyridyl)-4,5,6,7-tetrahydropyrazolo[1,5-a]pyrimidine-3-carboxylate

Step A: To a stirred solution of compound 1 (7.0 g, 44.3 mmol) in THF (100 mL) was added $n\text{-BuLi}$ (1.6 M hexane solution, 28 mL, 44.8 mmol) at -78°C . After the mixture was stirred for 30 min, compound 2 (6.34 g, 44.3 mmol) was added thereto. The resulting mixture was stirred at $-78--50^\circ\text{C}$ for 2h, quenched with saturated citric acid solution and extracted with AcOEt. The extract was successively washed with water and brine, dried over MgSO_4 and then concentrated in vacuo. The residue was chromatographed on silica gel with AcOEt/hexane (1:9) as an eluent to give 3.16 g (44% yield) of compound 3 as colorless liquid.

Step B: To a solution of compound 3 and compound 4 in methoxyethanol (60 mL) was added TFA (4.47 g, 39.2 mmol) with ice-water cooling. The mixture was refluxed for 12 h, diluted with AcOEt, and the mixture was washed with saturated NaHCO_3 solution, water and brine, dried over

MgSO₄, and then concentrated in vacuo. The residue was chromatographed on silica gel with AcOEt/hexane (1:4) as an eluent to give 2.03 g (36% yield) of compound 5 as colorless prisms.

5 Step C: A mixture of 5 (1.98 g, 6.96 mmol) and 10 % Pd-C (1.0 g) in EtOH (100 mL) was stirred for 2h under the H₂ atmosphere (balloon pressure). After the insoluble materials were filtered off, the residue was concentrated in vacuo to give the residue. Crystallization from
10 hexane/IPE gave the title compound 6 (1.00g, 48%) as colorless solid. ¹H NMR (CDCl₃, 200 MHz): 1.34 (3H, t, J=7.0 Hz), 4.26 (2H, q, J=7.0 Hz), 4.80 (1H, dd, J=11.4, 2.6 Hz), 6.39 (1H, s), 7.24-7.31 (1H, m), 7.51 (1H, d, J=7.6 Hz), 7.76 (1H, td, J=7.6, 1.8 Hz), 8.60-8.63 (1H, m).

15 Compounds of Examples 16-29, 439-447 and 924-938 shown in the Table 2, were prepared in a manner similar to that described in Example 15.

Example 435

N-(1-adamantyl)-7-ethyl-5-phenyl-7-(trifluoromethyl)-
4,5,6,7-tetrahydropyrazolo[1,5-a]pyrimidine-3-carboxamide

Step A: To a stirred solution of compound 1 (2.00 g, 6.00 mmol) in DCM (50 mL) was added triethylaluminum (2.0 M hexane solution, 18 mL, 36 mmol) at room temperature. After the mixture was stirred for 2 h, it was quenched with water, and extracted with AcOEt. The extract was successively washed with water and brine, dried over MgSO_4 and then concentrated in vacuo to give compound 2 (2.20 g, 100% yield) as yellow syrup. MS(ESI, m/z) 366 ($M+H$)⁺.

Step B: A mixture of compound 2 (2.20 g, 6.00 mmol), LiOH (0.51 g, 12.15 mmol), EtOH (50 mL) and H_2O (30 mL) was

stirred at 70 °C for 12 h, concentrated in vacuo, diluted with aq.citric acid solution and extracted with AcOEt. The extract was successively washed with water, saturated NaHCO₃ solution and brine, dried over MgSO₄ and then concentrated to give compound 3 (2.00 g, 100%) as colorless crystals. MS(ESI,m/z) 352 (M+H)⁺.

Step C: 1-Adamantylamine (0.72 g, 4.76 mmol) was added to a suspension of compound 3 (1.60 g, 4.74 mmol), WSC (0.91 g, 4.74 mmol), HOBt (0.64 g, 4.74 mmol) and DMAP (0.58 g, 4.75 mmol) in DMF (20 mL). The reaction mixture was stirred at 70 °C for 13 h and then concentrated in vacuo. The residue was chromatographed on silica gel with AcOEt/hexane (1/6) as an eluent to give compound 4 (0.71 g, 32 %) as colorless crystals. MS(ESI,m/z) 472 (M+H)⁺.

Step D: To a solution of 4 (0.58 g, 1.23 mmol) in EtOH was added NaBH₄ (0.2 g, 5.29 mmol) at room temperature. The whole was stirred at 60 °C for 3 h, concentrated in vacuo, diluted with water and extracted with AcOEt. The extract was successively washed with aq. NaHCO₃, water and brine, dried over MgSO₄ and then concentrated to give 0.43 g (74%) of compound 5 as colorless crystals. MS(ESI,m/z) 474 (M+H)⁺.

Compounds of Examples 436, shown in the Table 5, were prepared in a manner similar to that described in Example 435.

Step A: To a 250 mL round bottom flask equipped with magnetic stir bar and 2 addition funnels was added 1.0 g (6.44 mmol) of compound 1 by 3.5 ml of conc. hydrochloric acid and 7.0 ml of water. The solution was cooled to 0 °C and a solution containing 0.50 g (7.25 mmol) of sodium nitrite in 2 ml of water dropwise. Experiment 1

Strategy for cloning of the cDNAs encoding the human CaR

Strategy for cloning of the cDNAs encoding the human CaR is shown below. To amplify the cDNA encoding the N-terminal moiety of the human CaR, the synthetic DNA primers, Ca1-U : 5'-AGAGTCGACGCCACCATGGCATTATAGCTGCTGCTGG-3' and Ca1-L : 5'-AAATGAGCTCTCGGTTGGTGGCCTTGAC-3', were constructed. In this case, SalI site was added at the 5' end of amplified cDNA. To amplify the cDNA encoding the C-terminal moiety of the human CaR, the synthetic DNA primers, Ca2-U : 5'-AAACGAGCTCTCCTACCTCCTCCTCTTC-3' and Ca2-L : 5'-TCTGCGGCCGCTCCCTAGCCCAGTCTTCTCCTTCC-3', were constructed. In this case, NotI site was added at the 3' end of amplified cDNA. PCR was carried out by Hot Start method. The reaction solution of the upper phase was added of 1 pg of the human kidney-derived cDNA (TOYOBO), 0.3 mM dNTPs and 2.5 unit LA Taq DNA polymerase (Takara shuzo co.) and filled up to 30 μ l with water and buffer attached to the enzyme. To the reaction solution of the lower phase was added 12.5 μ M each of the synthetic primers and 0.5 mM dNTPs and filled up to 20 μ l with water and buffer attached to the enzyme. The reaction solution of the upper phase was added on the lower phase covered with an AmpliWax PCR Gem100 (Takara Shuzo Co.). The samples were subject to PCR amplification using a Thermal Cycler (Perkin-Elmer Co.).

The amplified cDNAs were confirmed by agarose gel electrophoresis.

Experiment 2

5 Preparation of CaR-expression CHO cells

The PCR products obtained in Experiment 1 were separated by agarose gel electrophoresis. The PCR products were excised and purified from the gel and subcloned into pT7Blue-T vector (Takara Shuzo Co.). The cDNA fragment
10 encoding the N-terminal moiety of the human CaR was released from the subcloned pT7Blue-T vector treated with SalI and SacI. The cDNA fragment encoding the C-terminal moiety of the human CaR was released from the subcloned pT7Blue-T vector treated with SacI and NotI. Using DNA
15 Ligation kit (Takara Shuzo Co.), these fragments were inserted between the site of SalI- and NotI- in the digested pMSR α neo vector. Thus, the pMSR α neo-CaR for animal cell expression was constructed.

Ten μ g of the pMSR α neo-CaR was added to the solution
20 containing 8×10^6 CHO-K1 cells, and transfection was carried out using Gene Pulser (0.4cm cuvette, 0.25kV, 960mF) (Bio-Rad Laboratories). The cells were cultured in HamF12 containing 10% fetal calf serum for one day. After passage, the cells were cultured in HamF12 containing 10% fetal and
25 500 μ g/ml Genetisine. The cells were seeded on 96-well plate

in 1×10^3 cells/well and transformants, CaR-expressing CHO cells, were selected in the selection medium.

Experiment 3

5 Selection of the CaR-expressing CHO cell line by calcium mobilization assay

A method for calcium mobilization assay is shown below. The CaR-expressing CHO cells were seeded on a 96-well white plate in 2×10^4 cells/well, followed by cultivation for 48
10 hours. After washing the cells with Phosphate-Buffered Saline, 100 μ l of buffer solution (120 mM NaCl, 22 mM NaHCO_3 , 6 mM KCl, 0.2 mM CaCl_2 , 1 mM MgCl_2 , 5 mM glucose, 5 mM HEPES (pH 7.4)) containing 5 μ M FuraPE3AM (Texas Fluorescence Laboratories) was added to the wells and kept
15 at 37°C for 1 hour. The cells were washed twice with Phosphate-Buffered Saline. After adding 180 μ l of the reaction buffer solution (130 mM NaCl, 5.4 mM KCl, 0.2 mM CaCl_2 , 0.9 mM MgCl_2 , 10 mM glucose, 20 mM HEPES (pH 7.4)) to the wells, 20 μ l of 60 mM CaCl_2 was added and
20 intracellular calcium concentration were measured with a fluorometric imaging plate reader (FDSS 2000, Hamamatsu photonics). One clone increasing intracellular calcium concentration was selected and used for the following experiment.

Experiment 4

GTP γ S binding assay

Preparation of membrane fraction is described bellow.

The human CaR-expressing CHO cells were inoculated to a
5 F500 flask in 1.8×10^5 cells/flask followed by cultivation
for 2 days. The cells were scraped with 10ml of Phosphate-
Buffered Saline containing 0.02% EDTA. After centrifugation
(2000 rpm, 10 min) of the cells, the cell pellet was
resuspended into 12 ml of homogenate buffer solution (10 mM
10 NaHCO_3 , 1 mM EDTA, 1x Protease inhibitor cocktail (pH 7.4))
and homogenized by PolytronTM (20000 rpm, 1 min). The cell
debris was removed by centrifugation (2000 rpm, 10 min),
and then the CaR-expressing cell membrane fraction was
collected by ultracentrifugation (Beckman 70 Ti type rotor,
15 30000 rpm, 1 hour).

The GTP γ S binding activity was measured as follows.
Twenty μg of the CaR-expressing cell membrane was incubated
with test compounds for 10min. The assays were carried out
at room temperature for an hour in a reaction solution
20 mixture containing 20 mM HEPES (pH.7.4), 100 mM NaCl, 1 mM
 MgCl_2 , 167 $\mu\text{g/ml}$ DTT, 5 μM guanosine 5'-diphosphate, 0.4 nM
[^{35}S]-guanosine 5'-(γ -thio) triphosphate ([^{35}S]-GTP γ S) and 6
mM CaCl_2 . The mixture was filtered through a GF/C filter.
After washing fourth with 300 μl of Phosphate-Buffered
25 Saline, the amount of [^{35}S]-GTP γ S bound to the filter was

measured using a Top-count scintillation counter.

Effects of test compounds on [³⁵S]-GTPγS binding were expressed in percentage terms. This was calculated from the equation $[100 \times (t' - b)] / (t - b)$ where t', t and b are values of [³⁵S]-GTPγS binding (dpm), t' in the presence of 6mM calcium and the test compound, t in the presence of 6mM calcium only and b in the absence of both 6mM calcium and the test compound.

The antagonist dose-dependently decreased [³⁵S]-GTPγS binding in membrane preparation. The agonist dose-dependently increased [³⁵S]-GTPγS binding in membrane preparation.

The results are shown in Table 7.
